Islandia, NY 11749
email: rcohen@kldcompanies.com

March 7, 2024   **Final Report, Rev. 3**   **KLD TR – 1381**

Introduction

Section 65302.15 of Assembly Bill (AB) 747, dated October 9, 2019, states that the safety element, as described in subdivision (g) of Section 65302, shall "identify evacuation routes and their capacity, safety, and viability under a range of emergency scenarios".

The City of Berkeley has contracted KLD Engineering, P.C. to analyze the capacity, safety, and viability of the evacuation routes within the city limits. The results of the analysis will help the City of Berkeley identify which evacuation routes are safest, have the largest capacity, and are the most viable under a variety of circumstances, as well as identify which evacuation routes may underserve the evacuating population. This report describes the data, assumptions, analysis, and results of the safety, capacity, and viability of the roadways within the City of Berkeley.

Data Sources

- The city street centerline dataset was provided by the city and is used as the basis for this analysis.
- The following datasets were utilized to analyze the safety of each evacuation route:
  - Crash data from the City of Berkeley Vision Zero high collision corridors within the city.
  - The street centerline data was provided by the city and was used to identify dead ends, narrow roads, and winding roads. In addition, the dead-end data provided by the city and those obtained from the road survey were also considered in this analysis.
  - The Pavement Conditions Index (PCI) was utilized to determine pavement quality on the roadways within the city. This data was provided by the city. Roadways with missing PCI data were supplemented with aerial imagery using data from neighboring roadways with similar characteristics/pavement conditions.
  - The International Roughness Index[1] (IRI) data from the Federal Highway Administration[2] (FHWA) was used to determine pavement quality on I-80.
  - National bridge and tunnel inventory from the Bureau of Transportation Statistics (BTS). The inventory includes information on bridge/ tunnel location, structure condition, year of construction, average daily traffic, etc.
  - Federal Emergency Management Agency's (FEMA) 100-year and 500-year flood zones[3]. The 100-year and 500-year flood zones identify areas that have a 1% and 0.2% chance of flooding, respectively, in any given year.

[2] https://geodata.bts.gov/datasets/highway-performance-monitoring-system-hpms-2020/about
[3] https://www.fema.gov/flood-maps

- o California Department of Conservation[4] earthquake zones and the United States Geological Survey (USGS) HayWired Scenario[5]. This dataset includes areas that are at risk for seismic hazards which include the following risks:
    - deep-seated landslide susceptibility based on estimates of rock strength and steepness of slopes,
    - liquefaction,
    - surface fault rupture,
    - and ground shaking.
  - o California Department of Conservation tsunami zones[4]. This dataset includes all populated areas that are at risk of tsunamis.
  - o Fire Hazard Severity Zones (FHSZ) data obtained from the City of Berkeley. FHSZ are scored based on factors that influence fire likelihood and fire behavior. Fire Zones 2 and 3 were considered at-risk in this study.
- The following datasets were utilized to analyze the viability of each evacuation route:
  - o Number and location of electric charging stations were obtained via PlugShare as referenced on the City's Electric Mobility website[6].
  - o Google Places was utilized to determine the number and location of gas stations throughout the city.
  - o Freeway ramps only exist within the city along I-80. The ramp locations are included in the street centerline data provided by the city.
- The following datasets were utilized to estimate the demand that would utilize each evacuation route:
  - o The latest census tract data from the U.S. Census Bureau.
  - o The permanent resident population is based on the 2020 U.S. Census population from the Census Bureau website extrapolated to April 2023 using annual growth rates that are computed from the 2022 Census population estimates.
  - o Data from the U.S. Census Longitudinal Employer-Household Dynamics (LEHD) from the OnTheMap Census analysis tool is used to estimate the number of employees commuting into the city.
  - o Data for Almeda County from the Highway Performance Monitoring System[7] (HMPS) 2020 was utilized to estimate the volumes on I-80 within the city limits.
  - o Total enrollment at UC Berkeley from 2019 to 2020[8] was utilized to estimate the number of student vehicles that would evacuate from the campus.
- The following datasets were utilized to analyze the demographics[9] of the neighborhoods surrounding each evacuation route:

---

[4] https://maps.conservation.ca.gov/cgs/#datalist
[5] https://earthquake.usgs.gov/education/shakingsimulations/hayward/M7.0.php#
[6] https://berkeleyca.gov/city-services/getting-around/electric-mobility
[7] https://geodata.bts.gov/datasets/highway-performance-monitoring-system-hpms-2020/about
[8] https://opa.berkeley.edu/campus-data/common-data-set
[9] The population demographics along each evacuation route can predict additional risks to people living along the route. For example, people living along evacuation routes in areas with higher rates of poverty may be at a higher risk than people living along evacuation routes in areas with lower rates of poverty due to the resources that are available to higher income people.

- o ESRI's ACS poverty status variables by census tract[10]. This dataset estimates the percentage of population with income lower than the federal poverty level at census tract level. The data is provided by the U.S. Census Bureau's ACS 2017-2021 5-year estimates.
- o ESRI's American Community Survey (ACS) vehicle availability variables by census tract[11]. This dataset shows the percentage of households without vehicles at census tract level. The data is provided by the U.S. Census Bureau's ACS 2017 – 2021 5-year estimates of household size by number of vehicles available.
- o California Department of Transportation housing and transportation affordability index[12]. This dataset measures the percentage of income devoted to housing and transportation for the regional typical household at the census tract level.
- o ESRI's ACS disability by type variables by census tract[13]. This dataset shows the percentage of the population with a disability at census tract level. The data is provided by the U.S. Census Bureau's ACS 2017-2021 5-year estimates of six different types of disability[14].

Assumptions

- Jenks Method of Natural Breaks[15] is used to develop the scaling factors, where applicable.

- Link centroids (midpoint) are used when applying factors of safety, demographics, and viability.

- For the analysis on pavement width (narrow roadways), the following assumptions were made:
  - o Parking stalls are 8 feet wide. Using the city's curb data for parking information, pavement width was reduced by 8 feet to account for roadways with street parking (or 16 feet if parking is permitted on both sides of the road).
  - o A minimum of 10 feet is necessary for large vehicles (delivery trucks, buses, etc.) to evacuate.

- For the viability analysis, the connectivity score is based on the following assumptions:

  - o The centroid (geometric center) of each Census block group was utilized as the representative trip origin.

  - o Shortest path chosen from each centroid to each exit leaving the city along a major evacuation route. (Some examples of exits leaving the city along a major

[14] The following disabilities are included: hearing, vision, cognitive, ambulatory, self-care, and independent living difficulties.
[15] The Natural Breaks (Jenks) identify class breaks as groups with similar values and maximize differences between classes. https://pro.arcgis.com/en/pro-app/latest/help/mapping/layer-properties/data-classification-methods.htm

evacuation route are I-80 eastbound at exit 13A/Buchanan Street and I-80 westbound at the junction with SR 13/Ashby Avenue.)

- For the viability analysis, the following assumptions were utilized to estimate the vehicular demand on a link:
  - The 2020 Census data, extrapolated to 2023, and 2020 employee estimates from OnTheMap, as well as 5-year ACS aggregate number of vehicles by block group, are used to determine the number of vehicles that are likely to use a given roadway segment.
  - Tourist vehicles are not included.
  - Employee and commuting student vehicle occupancies are assumed to be 1 employee per vehicle.
  - Public transit was not considered.
  - It was assumed that on campus students are included in the census data.
  - It was conservatively assumed that off campus students live within the City of Berkeley.
  - No reduction in commuters is considered for remote work and learning.

Analysis

Safety

There are several considerations when determining how safe a roadway is. For example, crash history can be a good indication of how well a roadway was designed. If an intersection is prone to side-impact collisions, it could be an indication of poor sight distance and, therefore, an unsafe roadway. Narrow and/or winding roadways were also considered a safety risk. These roadways can significantly impede evacuation since drivers often need to slow down to safely traverse these sections of roadway.

The safety factors were utilized to determine the overall safety of the evacuation routes within the city. Table 1 shows the safety factors, their associated scaling system (using Jenk's Law of Natural Breaks where appropriate), the weight applied (if any), and the description of each factor that was utilized in this study. Scales that ranged beyond 1 were normalized to fall between 0 and 1. **The higher the safety rating, the more unsafe a roadway segment is.** An overall safety rating was computed by summing each safety factor (multiplied by its weight, if applicable).

Figure 1 through Figure 6 show the various factors that were applied for the safety analysis and the results that were obtained.

Hazards

In addition to the roadway characteristics, roadways can be more or less unsafe than other roadways under different circumstances. For example, in rainy weather, a roadway that is in an area with a high landslide probability is likely to be more unsafe than a roadway in an area with low landslide probability. It should be noted that even if a route is exposed to one or more hazards, it may still need to be used to evacuate areas of the city. As such, the hazard factors are presented separately from the safety factors and were excluded in the overall safety rating.

Table 1 also presents the hazard factors, their associated scaling system (using Jenk's Law of Natural Breaks where appropriate), the weight applied (if any), and the description of each factor that was utilized in this study. Figure 7 through Figure 11 show the various factors that were applied for the hazard analysis and the results that were obtained.

Capacity

The ability of the road network to service vehicle demand is a major factor in determining how rapidly an evacuation can be completed. The capacity of a road is defined as the maximum hourly rate at which persons or vehicles can reasonably be expected to traverse a point or uniform section of a lane of roadway during a given time period under prevailing roadway, traffic and control conditions, as stated in the 2022 Highway Capacity Manual (HCM). This section discusses how the capacity of the roadway network was estimated.

For the purposes of this analysis, capacity is estimated along sections of roadway, rather than at intersections or ramp junctions. The capacity of roadway <u>sections</u>[16] is a function of roadway geometrics (e.g. number of lanes, grade, etc.), traffic composition (e.g., percent heavy trucks and buses in the traffic stream) and, of course, motorist behavior. The source material for the capacity estimates presented herein is contained in:

> 2022 Highway Capacity Manual (HCM)
> Transportation Research Board
> National Research Council
> Washington, D.C.

The evacuation route system in the city consists primarily of three categories of roads:

- Two-Lane roads: Local, State
- Multilane Highways/Roadways (at-grade)
- Freeways

Each of these classifications will be discussed. The roadway classifications, and resulting estimated capacities, are based on field observations, including number of lanes, collected during the road survey which was conducted in May 2023.

---

[16] This analysis is based on computed capacity alone and does not consider the time-varying demand impact on actual capacity.

Two-Lane Roads

Ref: HCM Chapter 15

Two lane roads (one lane in each direction) comprise the majority of roadways within the city. The per-lane capacity of a two-lane roadway is based on its speed. The speeds[17] and corresponding estimated roadway capacities for two lane roads are provided in Table 2. These estimates are essentially independent of the directional distribution of traffic volume. The HCM procedures then estimate LOS and Average Travel Speed.

Based on the field survey, aerial imagery, and on expected traffic operations associated with evacuation scenarios:

- Most sections of two-lane roads within the study area are classified as "Class I", with "level terrain"; some are "rolling terrain".
- "Class II" highways/roadways are mostly those within urban and suburban centers.

Multilane Roadways

Ref: HCM Chapter 12

Exhibit 12-8 of the HCM presents a set of curves that indicate a per-lane capacity ranging from approximately 1,900 to 2,300 pc/h, for free-speeds of 45 to 70 mph, respectively. Based on observation and estimation, the multilane roadways within the city service traffic with free-speeds in this range. Once again, for purposes of this analysis on multilane roadways, the actual time-varying speeds, the demand and capacity relationship, and the impact of control at intersections are ignored due to their dynamic nature. A conservative estimate of per-lane capacity of 1,900 pc/h is adopted for this study for multilane roadways within the city.

Freeways

Ref: HCM Chapters 10, 12, 13, 14

Chapter 12 of the HCM presents procedures for estimating capacity and LOS for "Basic Freeway Segments". Exhibit 12-37 of the HCM presents capacity vs. free speed estimates, which are provided below.

Free Speed (mph):	55	60	65	70+
Per-Lane Capacity (pc/h):	2,250	2,300	2,350	2,400

The inputs to the estimation of capacity are roadway geometrics and free-speeds. A conservative estimate of per-lane capacity of 2,250 pc/h is adopted for this study for freeways.

---

[17] Free flow speeds and number of lanes, as driven during the road survey in May 2023, were utilized to compute capacity. The impact of traffic control devices on free flow speeds is considered for two lane roadways within the City.

Chapter 13 of the HCM presents procedures for estimating capacity, speed, density and LOS for freeway weaving sections. Chapter 14 of the HCM presents procedures for estimating capacities of ramps and of "merge" areas. There are three significant factors to the determination of capacity of a ramp-freeway junction: The capacity of the freeway immediately downstream of an on-ramp or immediately upstream of an off-ramp; the capacity of the ramp roadway; and the maximum flow rate entering the ramp influence area. In most cases, the freeway capacity is the controlling factor. Values of this merge area capacity are presented in Exhibit 14-10 of the HCM and depend on the number of freeway lanes and on the freeway free speed. Ramp capacity is presented in Exhibit 14-12 and is a function of the ramp's free flow speed. Concepts in these chapters are utilized to estimate the capacity of freeway ramps within the city.

Viability

Viability is defined as the ability to function adequately. It is also defined as the ability to succeed or be sustained. As such, the viability of an evacuation route can be defined in several different ways. The following scores have been developed for this study to assess the viability of the roadways within the city. Table 3 presents each of the viability scores, their scales, and their descriptions.

Connectivity score: How well does a roadway connect you to an area of refuge or nearby city? Roadways that directly connect evacuees to places of safety are more *connected* and are considered more viable than roadways that do not. To determine how well connected each roadway is, ArcGIS's network analyst was utilized to find the shortest path from each trip origin (Census block centroid) to each trip destination (city exit along a major evacuation route). Once each route was computed from each origin (O) to each destination (D), the routes were spatially joined with each roadway link to determine the total number of origin-destination paths that traversed each segment. Roadway segments with more paths are more connected, and more viable, than roadway segments with less paths.

Accessibility score: How accessible is a roadway to evacuees? A freeway usually has a very high capacity and great connectivity, but if the ramps that give access to the freeway are 10 miles apart, it may not be the most viable evacuation route. For this reason, the number of connections, or intersections/ramp junctions, was considered in the accessibility score. To determine the number of connections or intersections for each route, the number of other links (roadway segments) that are connected to each link was computed. Nodes were created at the intersections of links. A spatial join was done to count the number of links that connect each node. Finally, a spatial join was conducted to assign the total number of connected links from connected nodes to their corresponding links. In addition, aerial imagery was used to verify the link and node connection. For ramps, if a roadway is a ramp or has a ramp connection, it was assigned a value of 5 for appropriate weight in the accessibility score. The accessibility score is the sum of the number of ramps and the number of connected links. The more intersections/connections/ramps a roadway has, the higher the accessibility score and the more viable the roadway is considered.

Service score: Does the roadway have the necessary commodities or services to sustain evacuees, like gas stations and/or electric charging stations? Roadways that have these types of commodities facilitate evacuation and, therefore, are more viable evacuation routes than roadways that do not have these types of commodities.

ArcGIS's network analyst was utilized to determine how far a roadway was from a service (gas or charging) station. For example, a roadway with a gas station score of 2 and a charging station score of 4 is a 2 minute drive from the nearest gas station and a 4 minute drive from the nearest charging station. The service rating is the sum of these two values.

Congestion score: A good way to measure the viability of an evacuation route is to determine if the population demand (residents, employees, students, and pass through traffic) that is expected to utilize the route will exceed the estimated capacity. For example, can the route service the demand in an evacuation, or will it operate below capacity and have bottlenecks and operational constraints?

The best way to answer these questions is with a traffic simulation model that uses algorithms to simulate real traffic behavior under a variety of circumstances. Currently, the City of Berkeley is conducting an evacuation time estimate (ETE) study to compute how long it would take to evacuate the city under different temporal and spatial conditions. This study utilizes a traffic simulation model. As part of this work effort, the congestion during evacuation conditions along each evacuation route can be assessed. This project is still ongoing, and as a result, the results of the project cannot be utilized to assess the congestion score, or viability, of the evacuation routes within the city at this time.

In the meantime, the evacuating vehicular demand can be estimated based on trip origins and this demand can be compared to the capacity[18] of the roadway segments within the vicinity of each origin.

The evacuating vehicular demand for each route was computed from Census data (population data extrapolated to 2023 and employment data from LEHD) in the proximity of the route. Resident and employee datapoints (converted to vehicles using assumed occupancies) within a quarter mile buffer of the roadway segment were assigned to each roadway segment as the vehicular demand to be serviced. In addition, pass through traffic along I-80 was estimated from annual average daily traffic counts collected by the US Department of Transportation along I-80.

This demand can fluctuate depending on the time of year, day of week, and time of day. For this reason, a minimum and maximum demand was estimated using scenario percentages for varying temporal conditions. For example, employees within the city peak between 9am and 5pm on weekdays and only about 10% of employees may be present on weekends and in the evening. It should be noted that the minimum demand represents when UC Berkeley is not in session; the maximum demand represents when UC Berkeley is in session.

---

[18] As computed in the *Capacity* section of this report.

Since vehicles will load onto the roadway network over time, rather than all at once, the mobilization distribution[19] was computed from an online demographic survey of residents and employees/commuting students within the City of Berkeley. Figure 12 shows the mobilization curve that was utilized. The maximum demand (volume) was computed for each roadway segment based on the highest hourly mobilization percentage (57% for residents [between 45 minutes and 1 hour and 45 minutes after the order to evacuate] and 100% for employees and commuting students [in the first hour]).

The volume was then divided by the total roadway capacity to compute the volume-to-capacity (v/c) ratio for each roadway segment. The v/c ratio was utilized as the congestion score for the maximum and minimum demand, the higher the congestion score, the lower the viability.

Vulnerability

Although not specifically a roadway safety, capacity or viability consideration, the demographics of the neighborhoods that surround the roadway could be indicative of areas that are more vulnerable and may face challenges when evacuating. For example, areas with less vehicle availability are likely to require public transit and may face more challenges than those areas with enough vehicles to sufficiently evacuate the household in a personal vehicle. These factors were considered separately from the safety, capacity or viability factors but were included in this analysis for a complete picture. The vulnerability factors and their scaling system (using Jenk's Law of Natural Breaks where appropriate), the weight applied (if any), and their description are included in Table 4. **The higher the vulnerability rating, the greater vulnerability of the population living along a roadway segment.** An overall vulnerability rating was computed by summing each factor (multiplied by its weight, if applicable).

through show the various factors that were applied for the vulnerability analysis and the results that were obtained.

Results

Appendix A provides a summary (sorted by street name[20]) of the average[21] overall safety rating, capacity, viability score and vulnerability rating by roadway name. Each of the various components and factors that were utilized to compute the safety, capacity, and viability of each roadway segment, as well as the overall safety, capacity, and viability scores of each roadway segment, were provided to the City in electronic format.

While the safety, capacity, viability, and vulnerability varies somewhat within individual street segments on a particular roadway, the following evacuation routes have the highest capacity, are relatively safe, and are the most viable across the entire length of the roadway, see Figure 17:

- University Ave

---

[19] The notification distribution was assumed over a 30-minute period due to the presence of wireless emergency alerts within the city and based on survey responses.
[20] The City's naming conventions within the centerline dataset were adopted with minimal changes.
[21] Each value shown is the average of all roadway segments that share that street name.

- Adeline St
- Ashby Ave (SR13)
- Cedar St
- Interstate 80 (I-80)
- San Pablo Ave (SR 123)
- Sacramento St
- Claremont Ave
- Marin Ave

Safety

Each of the safety risk scores were summed (with specified weights, if necessary) to obtain an overall safety rating for each roadway segment. Those roadway segments that have the highest overall score are the most unsafe roadway segments. Those with lower scores are safer. Figure 18 shows the overall evacuation safety ratings for each of the roadway segments within the city. Jenk's Law of Natural Breaks was used to develop the 4 thresholds of overall safety. Those roadways with the highest safety score (2.3 - 3.7) are shown in red and represent the roadways with the highest exposure to traffic fatalities, narrowest width, tightest turns, steepest slopes, poorest pavement condition and/or are located above or below a bridge or tunnel. The least safe roadways are within the hills and along Panoramic Way. These roadways are extremely narrow, winding, and steep. Many of the roadways within the flats, including San Pablo Ave, have poor or very poor pavement conditions, giving them a higher *unsafe* rating. The safest roadways are Frontage Rd, University Ave, and Adeline St.

Hazards

Each of the hazard risk scores were summed (with specified weights, if necessary) to obtain an overall hazard rating for each roadway segment. Those roadway segments that have the highest overall score have the highest exposure to flooding, landslides, earthquakes, tsunamis, wildfires. Those with lower scores are less exposed. Figure 19 shows the overall hazard ratings for each of the roadway segments within the city. The safest roadways are in central Berkeley between San Pablo Ave and the foothills of the mountains, including Hopkins St, Shattuck Ave, Adeline St, as well as parts of Cedar St, University Ave, and Ashby Ave. Roadways west of San Pablo Ave are exposed to water related hazards like flooding and tsunamis. Roadways in the mountains are exposed to fires, landslides, and more severe ground shaking.

Capacity

Figure 20 shows the capacity of each roadway segment within the City of Berkeley based on the field observations collected in May 2023, including the number of moving lanes on each roadway. I-80 has the highest capacity, followed by multilane major arterials like San Pablo Ave, University Ave, Shattuck Ave/Adeline St, Sacramento St, Telegraph Ave, and Claremont Ave. The vast majority of roadways within the city are single-lane collectors with a free flow speed of 45mph or less and a capacity of approximately 1,700 passenger cars per hour or less. In the hills, free flow speeds are 20 mph or less and capacities are 900 passenger cars per hour or less.

Viability

Figure 21 displays the connectivity score for the roadways within the city. In the figure, thicker roadways provide more origin-destination connections than thinner roadways and are, therefore, more connected. The most connected roadways are Sacramento St, Ashby Ave (SR 13), Martin Luther King Jr Way, Monterey Ave, Piedmont Ave (in Oakland), and Marin Ave. University Ave, Dwight Way and Cedar St are very connected as well.

Figure 22 displays the results of the accessibility score. Most of the roadways between I-80 and San Pablo Ave, South Berkeley, parts of central and north Berkeley, and I-80 are very accessible. Berkeley Hills and the eastern part of the city are not very accessible since they have limited connections to major roadways and very limited connections to the east of the city due to the mountainous terrain. Some of the most accessible roadways are I-80, Marin Ave, Shattuck Ave/Adeline St, and University Ave.

Figure 23 displays the results of the service score. Roadways west of San Pablo Ave, in the vicinity of University Ave, and in the vicinity of Shattuck Ave and Adeline St have the highest scores due to the density of gas and electric charging stations along these roadways.

Figure 24 and Figure 25 display the congestion scores[22] (v/c) for the maximum and minimum estimated effective demand during an evacuation event (respectively) converted to Level-of-Service (LOS), which is a term used to describe the operating conditions of a roadway. The LOS shown in these figures is based on the Highway Capacity Manual (HCM) rounded to the nearest tenth. As shown in these figures, during an evacuation, many of the roadways within the city will operate at LOS F and experience significant congestion. In both cases, the major arterials, like San Pablo Ave (SR 123), Sacramento St, University Ave, Adeline St, Ashby Ave (SR13), and Claremont Ave can better service the evacuating demand than the smaller, local streets within the heart of the city. As such, these roadways are more viable evacuation routes. During the case with minimal demand, and less pass-through traffic on I-80 (at night, for example), I-80 becomes one of the most viable evacuation routes as shown in Figure 25.

Vulnerability

Each of the vulnerability risk scores were summed (with specified weights, if necessary) to obtain an overall vulnerability rating for each roadway segment. Those roadway segments that have the highest overall score are the areas that could potentially have the most difficulty and/or challenges evacuating. Those with lower scores are less likely to have difficulty and/or challenges evacuating. Figure 26 shows the overall vulnerability ratings for each of the roadway segments within the city. Jenk's Law of Natural Breaks was used to develop the 4 thresholds of overall vulnerability. Those roadways with the highest vulnerability score (2.8 – 3.8) are shown in red and represent the roadways that are within areas with the most poverty, the least amount of income spent on transportation, the lowest vehicle availability and the highest population with disabilities.

---

[22] It should be noted that this methodology treats the evacuation of the city in a vacuum ignoring possible, simultaneous evacuation in areas adjacent to the city.

Table 1. Safety and Hazard Factors

Factor	Scale	Description
	Safety Factors	
Collisions	0 - No	The City of Berkeley Vision Zero collisions data was utilized to determine corridors with high collision rates. This data was spatially joined with the roadway segments to identify which roadways had the most, or any, collisions. Roadways with more collisions may be indicative of poor roadway design. Those roadways with high collision rates were assigned a value of 1; those corridors that did not have high collision rates were assigned a value of 0. See Figure 1.
	1 - Yes	
Pavement Width	0 – Not Constrained	The city centerline dataset was utilized to determine which roadways were narrow/constrained (with a travel lane of less than 10 feet wide[23]). Roadways that were considered not constrained (less than 10 feet wide) were assigned a value of 0. Those roadways which are considered constrained (meet or exceed 10 feet wide[24]) were assigned a value of 1. See Figure 2.
	1 – Constrained	
Curvature	0 – greater than or equaled to 81 feet	The curvature of the roadway was calculated based on its geometry. The radius of the circumscribed circle of three sequential points was computed and assigned to the midpoint of those three points. The roadway segment between two points was assigned the average of the two radii of the points in which it connects. A threshold of 81 feet[25] was selected as the minimum radius. See Figure 3.
	1 – less than 81 feet	
Slope	0.0 – 2.3	The slope of the roadway was also considered. Slopes are represented as a percentage (rise/run x 100). Roadways with steep slopes can be more dangerous than roadways with shallow slopes. As such, larger slopes were assigned a higher value than smaller slopes. A weight of 0.33 is applied to this factor to normalize the results between 0 and 1. See Figure 4.
	2.4 – 7.0	
	7.1 – 15.2	
	15.3 – 37.1	

---

[23] Based on discussions with staff from the City's Public Works and Fire Departments, a viable evacuation travel lane width of 10 feet was chosen to account for larger vehicles (8 feet wide) and sideview mirrors. It is assumed that even larger vehicles (10 feet wide) are operated by professional drivers with a higher degree of skill to reduce or eliminate driver error.

[24] Pavement width was utilized (with modifications made for side street parking). Eight feet of parking was removed from the pavement width for single side street parking and 16 feet was removed for street parking on both sides of the road. Eight feet was used since the typical width for a standard parking space is 8 feet. Although a width of 7.5 feet has been used to provide a balance among users, eight feet was used as vehicles are not always parked well, may not be parked in contact with the face of the curb or vegetation, and throughout the day, large vehicles may be parked on the side of the street. Overhanging vegetation was not accounted for.

[25] Table 3-7 of the 2018 AASHTO Policy on Geometric Design of Highways and Streets indicates the minimum radii for a curve with a design speed of 20mph is 81 feet. Based on the data collected during the road survey, the speed travelled on these curves was 20mph or less.

Factor	Scale	Description
Pavement Quality	0 – Very Good	Roadways with poor pavement quality can be more unsafe than roadways with good pavement quality. As such, the quality of the pavement was also considered in the safety analysis. Pavement quality was rated as unpaved, poor, fair/acceptable, and good. Unpaved and poorly rated roadways were rated higher than fair and good rated roadways. A weight of 0.33 is applied to this factor to normalize the results between 0 and 1. See Figure 5.
	1 - Good	
	2 - Poor	
	3 – Very Poor	
Bridges and Tunnels	0 - No	Bridges and tunnels are at risk of collapsing, making the roadways that traverse under or over them unsafe. The roadway segments that contained a bridge or tunnel were given a factor one 1. The remaining roadway segments were assigned a value of 0. Since all bridges (5) and tunnels (1) within the city are currently rated as 'fair', this factor was given a weight of 0.5. See Figure 6.
	1 - Yes	
Hazard Factors (excluded from overall safety rating)		
FEMA 100-Year and 500-Year Flood Hazard Areas	0 - not within a flood zone	The data depicts the FEMA 100-year and 500-year flood risk zones for Alameda County. The 100-year flood plain is the area with a 1% chance of flooding in any given year, while the 500-year flood plain is the area with a 0.2% chance of flooding in any given year. Roadways within a 100-year flood plain are at a higher risk, and are more unsafe, than roadways within a 500-year flood plain. It should be noted that none of the roadways within the city are within the 100-year flood zone. See Figure 7.
	0.2 - 500-year flood zone	
	1 - 100-year flood zone	
Landslide Hazard Areas	0 – 0.04 – Very low or none	The statewide landslide inventory shows many of the landslides mapped by CGS and others over the past 50 years. The database focuses on deep-seated landslides. Rock strength and slope are combined to create classes of landslide susceptibility. These classes express the generalization that on very low slopes, landslide susceptibility is low even in weak materials, and that landslide susceptibility increases with slope and in weaker rocks. Higher rates of landslide susceptibility include very steep slopes in hard rocks, and moderate to very steep slopes in weak rocks. Roadways with medium or high landslide susceptibility are less safe than roadways with low or very low (or no) landslide susceptibility. See Figure 8.
	0.05 – 0.12 - Low	
	0.13 – 0.22 - Medium	
	0.23 – 0.34 - High	

Factor	Scale	Description
Earthquake Hazard Risk	0.67 - Severe	HAZUS[26] results of an earthquake scenario on the Hayward Fault. These results include impacts due to ground shaking, landslide, and liquefaction. The results are measured in Modified Mercalli Intensity (MMI) which is composed of twelve levels that increase from imperceptible shaking to catastrophic destruction. The MMI rating is divided by 12 to scale the results from 0 to 1. The entire city falls either in severe (8) or violent (9) ground shaking. See Figure 9.
	0.75 - Violent	
Tsunami Hazard Areas	0 - No	The Tsunami hazard areas are developed for all populated areas at risk to tsunamis in California and represent a combination of the maximum considered tsunamis for each area. "No" indicates the roadway is not within a tsunami hazard area. "Yes" indicates the roadway is within a tsunami hazard area. See Figure 10.
	1 - Yes	
Fire Hazard Severity Zone	0 – Zone 1	FHSZ are scored based on factors that influence fire likelihood and fire behavior. Fire Zones 2 and 3 were considered at-risk in this study. Roadways that were not within Zones 2 or 3 are assigned a value of 0. Roadways within Zone 2 are assigned a value of 0.5 and those roadways within Zone 3 are assigned a value of 1. See Figure 11.
	0.5 – Zone 2	
	1 – Zone 3	

Table 2. Capacity for Two Lane Roads

Speed (mph)	Capacity (pc/h)
5	225
10	450
15	675
20	900
25	1,125
30	1,350
35	1,575
40+	1,700

---

[26] Hazards US software developed by the Federal Emergency Management Agency (FEMA).

Table 3. Viability Scores

Score	Scale	Description
Connectivity	1 - 187	Roadways that directly connect evacuees to places of safety are more connected and are considered more viable than roadways that do not. The scale of this score is based on the number of origin-destination connections that are made.
	188 – 519	
	520 – 1,023	
	1,024+	
Accessibility	0 - 3	The more intersections/connections/ramps a roadway has, the higher the accessibility score and the more viable the roadway is considered. Ramps were assigned a value of 5 for weighting purposes.
	4 - 5	
	6 - 7	
	8 - 11	
Service	2 - 4	Roadways that have gas stations and/or charging stations readily accessible help evacuees maintain their evacuation and, therefore, are more viable evacuation routes than roadways that do not have these types of commodities. The scores represent the sum of the driving time to the nearest gas station and charging station. Roadways that are furthest from a gas or charging station have a higher score and are less viable.
	5 - 8	
	9 - 12	
	13 - 17	
Congestion	LOS A (0 – 0.1)	The congestion score compares the demand (volume) against the capacity to see how the roadways will operate under evacuation conditions. This metric is called the v/c ratio. The Highway Capacity Manual provides an equivalent Level-of-Service (LOS) that ranges from A (free flow conditions) to F (bumper to bumper traffic) based on the characteristics of the roadway. This concept was used to develop general thresholds for the congestion score, rather than Jenk's Law of Natural Breaks.
	LOS B (0.1 – 0.2)	
	LOS C (0.2 – 0.4)	
	LOS D (0.4 – 0.6)	
	LOS E (0.6 – 0.95)	
	LOS F (0.95+)	

Table 4. Vulnerability Factors

Factor	Scale	Description
Poverty	Low (0.6% - 7.9%)	The poverty data estimates the percentage of population with income lower than the federal poverty level at the census tract level. The data is provided by the U.S. Census Bureau's American Community Survey (ACS) 2017-2021 5-year estimates. Areas with high percentages of poverty are more likely to have evacuation challenges and, therefore, have a higher vulnerability rating. See Figure 13.
	Medium (8.0% - 15.3%)	
	High (15.4% - 26.9%)	
	Very High (27.0% - 64.3%)	
Housing and Transportation Income	Low (0.0%)	The H+T income indicator measures the percentage of income devoted to housing plus (+) transportation for the regional typical household at the census tract level. The latest data (as of 2017) for this indicator were collected directly from the Housing and Transportation Costs (H+T) Index webpage. Areas with higher H+T have dedicated a higher percent of their income to housing and transportation and are not likely to have evacuation difficulties. As such, areas with low H+T percentages have a higher vulnerability rating. See Figure 14.
	Medium (0.1% - 45.0%)	
	High (45.1% - 58.0%)	
	Very High (58.1% - 76.0%)	
Vehicle Availability	Low (0.0% - 5.1%)	The data shows the percentage of households with no vehicles at the census tract level. The data is provided by the U.S. Census Bureau's ACS 2017-2021 5-year estimates of household size by number of vehicles available. These individuals are more likely to depend on public transit or need transportation assistance in an evacuation. As such, areas with high percentages of households with no vehicles are assigned a higher vulnerability rating than those with lower percentages. See Figure 15.
	Medium (5.2% - 14.0%)	
	High (14.1% - 25.5%)	
	Very High (25.6% - 71.0%)	
Population with Disabilities	Low (3.8% - 7.8%)	The data shows the percentage of population with a disability at the census tract level. The data is provided by the U.S. Census Bureau's ACS 2017-2021 5-year estimates of six different types of disability (hearing, vision, cognitive, ambulatory, self-care, and independent living difficulties). Individuals with disabilities are more likely to have difficulty evacuating. Areas with higher populations with disabilities are given a higher vulnerability rating. Since this factor has such low scaling, a weight of 2 was applied to this factor. See Figure 16.
	Medium (7.9% - 9.6%)	
	High (9.7% - 14.6%)	
	Very High (14.7% - 18.7%)
